

Lies, damn lies, and genomics

Navigating your data, your perceptions and reality

Christopher West Wheat
Professor at Department of Zoology

Career trajectory

- 1995 – 2001 PhD California
- 2002 – 2005 Postdoc Germany
- 2005 – 2008 Postdoc Finland
- 2009 – unemployed 4 month, spent all savings
 - > 50 job applications, 1 grant application
- 2009 – visiting scientist Germany
 - 1 job offer UK, 1 grant in Finland
- 2012 – Assistant Prof. at Stockholm University
- 2022 – Full Professor

What was important?

- Being able to move, chase the money & get skills
- Learning how to believe in my ideas/skills
- Writing lots of grants, get used to rejections

I was able to put science first & have fun along the way

Something you likely would
never know about me

I am a Judge for the
American Field Trial Clubs of America
(since 2003)

Ecological & Evolutionary Functional Genomics

Circadian and seasonal clock evolution

Butterfly-plant coevolution dynamics

Alternative life history switches

Goals of this lecture

- Present a critical view of things genomic
- Make you uncomfortable by sharing some of my nightmares with you
- Critically assess findings and expectations in light of easy errors and publication biases
- Encourage you to be part of the solution

Disclaimer

I'm a positive person

I love my job and the work we all do

My goal here is to provoke you to think critically

What if

Would that
impact your
science?

50% of your
favorite studies
were not
repeatable?

John H. McDonald & Martin Kreitman

Adaptive protein evolution at the *Adh* locus in *Drosophila*

John H. McDonald & Martin Kreitman

Department of Ecology and Evolutionary Biology, Princeton University,
Princeton, New Jersey 08544, USA

We suggest that these excess replacement substitutions result from adaptive fixation of selectively advantageous mutations.

TABLE 2 Number of replacement and synonymous substitutions for fixed differences between species and polymorphisms within species

	Fixed	Polymorphic
Replacement	7	2
Synonymous	17	42

A G-test of independence (with the Williams correction for continuity)¹ was used to test the null hypothesis, that the proportion of replacement substitutions is independent of whether the substitutions are fixed or polymorphic. $G=7.43$, $P=0.006$.

Colias eurytheme

My PhD: use this DNA based molecular test of selection on a classic example of balancing selection from allozyme era

From DNA to Fitness Differences: Sequences and Structures of Adaptive Variants of *Colias* Phosphoglucose Isomerase (PGI)

Christopher W. Wheat,*†¹ Ward B. Watt,*† David D. Pollock,*†² and Patricia M. Schulte*†³

*Department of Biological Sciences, Stanford University and †Rocky Mountain Biological Laboratory, Crested Butte, Colorado

Among *C. eurytheme* and *C. meadii* PGI sequences, we find 126 synonymous and 20 nonsynonymous polymorphic sites. From their ratio, 6.3:1, neutrality predicts ~ 13 synonymous fixations alongside the two observed interspecies nonsynonymous fixations. But, *no* fixed synonymous sites were found (above). These data differ significantly by Fisher's exact test ($P = 0.021$), following Moriyama and Powell (1996) and by Goldstein's (1964) exact binomial test, $x^* = 3.41$, $P = 0.0006$.

30 years later, these MK test results in *Drosophila melanogaster* were revisited

ARTICLES

PUBLISHED: 13 JANUARY 2017 | VOLUME: 1 | ARTICLE NUMBER: 0025

Experimental test and refutation of a classic case of molecular adaptation in *Drosophila melanogaster*

So

Does this
happen
only in
bugs?

my PhD chased
an adaptive story
lacking a rigorous
foundation

If the biomedical science has the most money and oversight, then

Their findings should be robust:

- **Repeatable effect sizes**
- **The same across different labs**
- **The same across years**

Publication replication failures

- Of 49 most cited clinical studies, 45 showed intervention was effective
 - Most were randomized control studies (robust design)
- Mouse cocaine effect study, replicated in three cities
 - Highly standardized study

Publication bias can increase effect size

What if there is no replication?

What is most likely to publish first & where?

The vicious cycle of power analysis and publication bias

Why Most Published Research Findings Are False

Ioannidis 2005 Plos Med.

A research finding is less likely to be true when:

- the studies conducted in a field have a small sample size
- when effect sizes are small
- when there are many tested relationships using tests without *a priori* selection
- where there is greater flexibility in designs, definitions, outcomes, & analyses
- when there is greater financial and other interest and prejudice
- when more teams are involved, all chasing after statistical significance by using different tests

Which of these apply to genomics?

- ✓ the studies conducted in a field have a small sample size
- ✓ when effect sizes are small
- ✓
 - when there are many tested relationships using tests without *a priori* selection
- ✓ where there is greater flexibility in designs, definitions, outcomes, & analyses
 - when there is greater financial and other interest and prejudice
- ✓ when more teams are involved, all chasing after statistical significance by using
- ✓ different tests

But ...

surely, this doesn't apply to genomics

or does it?

Outline

- Why replication failures are happening in genomics
- Why we are responsible for most of this
- Steps we can implement to overcome these problems

8 disease genes first reported with $P < 0.05$

Ioannidis, J. P., E. E. Ntzani, T. A. Trikalinos, and D. G. Contopoulos-Ioannidis. 2001. Replication validity of genetic association studies. *Nat Genet* 29:306–309.

There are lies, damn lies, and

But wait, is that fair?

Are these really lies?

Where does this replication problem come from?

- Population heterogeneity
 - Space and time
- Publication culture
 - Large & significant effects publish fast with high impact
 - Small & non-significant effects publish slow, rarely, and with low impact
 - Technology and methods move faster than rigorous error modeling

Where does this MOST bias come from?

YOU!!

And me All of us

Its arises from humans doing science

The way we think

The way our institutions work

Apophenia

The tendency to seek and see patterns in random information and view this as important

Story telling of the
false positives

Genomics is too big to fail

- Making errors is extremely common
- Errors almost always result in highly significant results
- Studies in non-model species are rarely replicated

Question your bioinformatics before falling in  love with your results

When results are better than you could have dreamed,

Publications with significant human error that have not been retracted

Microbiome analyses of blood and tissues suggest cancer diagnostic approach

- Found strong association between microbial species and 33 different cancer types
 - based on a large collection of DNA and RNA sequencing samples taken from human cancers and normal tissues
- Used sophisticated machine-learning method to create highly accurate classifiers
 - Microbes could distinguish among tumor types

Poore et al. 2020; Spich-Poore et al. 2021; Gihawi et al. 2023

Diagnosis

Opportunities for microbes to affect cancer care.

Reported findings:

- led to a flurry of papers describing microbial signatures of different cancer types.
- Many of these reports are based on flawed data that, upon re-analysis, completely overturns the original findings.
- Re-analysis shows that most of the microbes originally reported as associated with cancer were not present at all in the samples.
- The original report of a cancer microbiome and more than a dozen follow-up studies are likely to be invalid.

Over-counts of bacteria were due to human reads that erroneously matched bacteria

A huge artifact arose from omitting the human genome from the analysis database (Kraken)

Gihawi et al. 2023 for text above

How can we improve reproducible findings?

Work better as a community, check each others code and post our code

As author, as supervisor, as reviewer, as Associate Editor, make sure all studies you touch :

- Have all code and raw data open source
- Analyzed datasets open source
- Methods clearly described

HAVE YOU EVER TRIED TO PUBLISH A REPRODUCTION ATTEMPT?

Although only a small proportion of respondents tried to publish replication attempts, many had their papers accepted.

● Published ● Failed to publish

Most popular strategy for replication was having different lab members redo work

Baker 2016 Is there a reproducibility crisis?

Of the few that tried to publish replications, many had papers accepted!!

HAVE YOU ESTABLISHED PROCEDURES FOR REPRODUCIBILITY?

Among the most popular strategies was having different lab members redo experiments.

**So ... there are lots of high-profile,
non-repeatable studies out there ...**

**Much of this is scientific progress ... we are
not perfect, just doing what we can**

**Thus .. calibrate your expectations, approaches,
be careful & stay humble**

What is your personal error rate?

I assume mine is 12%

therefore I perform many sanity & error checks to catch the errors I WILL MAKE, so my effective rate is much lower

"You have to validate what you create"

Erik Garrison

What other biases might we suffer from?

We're basically a rather lost, self domesticated chimp

<https://www.babyanimalprints.com/collections/monkeys-and-apes-black-and-white/chimpanzee>

We're basically a rather lost, self domesticated chimp

We're very likely to :

- see patterns when none exist
- think we can predict the future, cause we think we know how things work ... like:
 - gravity, your car, sunsets
 - weather, the stock market, Covid ...
 - the central dogma

Hindsight bias

the I knew-it-all-along effect

the tendency,
after an event has occurred,
to see the event as having been predictable,
despite there having been no objective basis
for predicting it.

Three Levels of Hindsight Bias

I KNEW
that would happen

The central dogma

But, can we, in a novel species :

- Predict gene expression level from DNA alone?
- Predict when / where a gene will be expressed from DNA alone?
- Write a protein that will do a specific enzymatic reaction, or several?

Going from peptide sequence to catalytic function ...

"We don't know how to write that way"

Beethoven's hand written sheet music

Quote in Nobel Prize lecture, 2018
<https://youtu.be/6hOZ5e0g9Uo>

Francis Arnold
Nobel Prize winner (2018)

inventors of AlphaFold were awarded the Nobel Prize for developing an AI model to solve a 50-year-old problem: predicting proteins' complex structures

nature

Article | [Open access](#) | Published: 08 May 2024

Accurate structure prediction of biomolecular interactions with AlphaFold 3

Can model protein protein interactions, along with other molecules

Did AI Solve the Protein-Folding Problem?

Open question is whether AlphaFold has actually discovered something meaningful about the physics of protein folding that humans haven't

"If we can predict how proteins fold without understanding how they do it, are we even legitimately doing science anymore, or is it something different?"

"We're able to get the practical benefits, but we're not necessarily gaining intellectual benefits"

<https://magazine.hms.harvard.edu/articles/did-ai-solve-protein-folding-problem>

In sum, we think we how things work...

... but biology is exceptionally complex

Three Levels of Hindsight Bias

I knew that correlation had to exist, it just makes sense

Of course this gene works the way its annotation says

AlfaFold can predict structures, now we understand enzymes

Data source: AlphaFold/EMBL-EBI/PDB Q8W3K0/Royal Society of Chemistry

How many have used AI to help with their coding?

Where does the training set for these answers come from?

Does that matter?

ChatGPT 4o

Can you draw me an image that contains a group of clocks showing the time of 3 minutes past 12

ChatGPT

Draw me a picture of a person
writing with their left hand.

I said left hand not the right!

Why is AI getting these simple things wrong ..

It's the training set and that has huge implications for most of your work

What species has the largest bioinformatics community?

Human biomedical studies drive the training set that inform all of your bioinformatic answers from ChapGPT

Use AI, verify the code works, then modify for your species

This is a piece of toast

Non-random patterns are abundant in genome scale data

Null models & controls are very difficult to get “right”

Analyses easily generate results that arise from
diverse non-biological causes

So .. how do we avoid Apophenia?

- Double check your data, analysis parameters / settings
 - Plot your data, look at it, does it make sense on 1st principals?
- Genome scale patterns are just hypotheses
 - Explore independent datasets, tools, approaches
 - biological samples, simulations, DNA vs. protein results
 - Manipulation: functional validation via manipulation of genes, pathways
 - Experimental evolution, CRISPR KOs, environmental perturbations

PSMC analysis of single genome for demographic trends

a very common analysis in the literature
basis of many evolutionary stories, conservation concerns

What can you do with 240 mammalian genomes?

Zoonomia

Assessed how historical effective
population size (N_e)
impacts heterozygosity
in relation to IUCN conservation
status

Dramatic peaks followed by even more extreme population collapses

- pattern occurred across
- distantly related turtle species around the globe and its existence
- was consistently supported based on bootstrap replicates

Authors decided to explore if their bioinformatic choices could be generating cross species pattern

- Input
 - used simulations of genomic data
- Tool settings
 - explored range of run settings (default vs. others)

Dataset simulations were used to explore what is being detected

- simulated diploid genomes ($n=30$) from a population with a population history having pronounced increase / decrease (black)
- Analysis never recovered peak on simulated data, even though it had that exact history (red)

Method not working the way it should ...

Explored PSMC run parameters

- default settings optimized for humans
- default setting fixes the first 4 atomic time intervals to first time window.
- infers a single N_e for a large first time window and cannot model population size changes during this time.

*if population declines within the first 4 time intervals,
the model likely overcompensates by producing
exaggerated N_e estimates in the previous time window*

when changing default settings to those
that better fit their species

all peaks/crashes go away

see the paper for analysis suggestions

They also re-ran published data

documenting widespread problem in the literature ...

Current Biology

Avoidable false PSMC population size peaks occur across numerous studies

Highlights

- We detected and solved a common artifact in PSMC and related methods
- Default PSMC parameters frequently cause false peaks in recent population histories
- New methods perform better but do not always avoid this artifact
- Users should test multiple parameter settings that split the first time window

Authors

Leon Hilgers, Shenglin Liu,
Axel Jensen, ..., Regev Schweiger,
Katerina Guschanski, Michael Hiller

Test your hypotheses in independent ways

- Genomic datasets:
 - Are observational data where patterns observed have been created by events unknown to us
 - This is similar to all studies using observational data
 - Very susceptible to false positives and just so stories
 - Extremely large P-values can arise from extremely weak patterns, so ask yourself, does the effect and effect size have biological meaning?

Test your hypotheses in independent ways

- Derive hypotheses from your genomic results, then
- Test these hypotheses using relevant manipulations
 - Simulated data, parameter exploration
 - Functional validation via manipulation of genes, pathways, environments ... real hypothesis testing!!
 - Experimental evolution, CRISPR KOs, environmental perturbations
- If you can't manipulate, at least triangulate!

Triangulation

Robust research needs many lines of evidence

Replication is not enough

Munafò and Smith 2018 Robust research needs many lines of evidence

Triangulation

Robust research needs many lines of evidence

Replication is not enough

Munafò and Smith 2018 Robust research needs many lines of evidence

Triangulation

- Use different approaches to address the same hypothesis, or extensions of hypothesis
- Sources of bias for each approach should be explicitly acknowledged, in opposite directions, and independent
- Results from more than two approaches are ideally compared
- As genomics gets faster/cheaper, invest savings in validation

Buckle-Up for another bioinformatic journey

- Using a new genomics technique
 - miRNA
- Trying to understand what is best practice
- Worked hard to triangulate upon what's a biological signal vs. bioinformatic artifact
- Uncovered serious problem in the non-model community

IN PHYSIOLOGY OR MEDICINE 2024

Victor Ambros

Gary Ruvkun

**“for the discovery of microRNA
and its role in post-
transcriptional gene regulation”**

miRNAs

destabilize mRNA

sculpt the pool of mRNA

are a key part of regulatory networks

metazoans can't live without'em

The role of
miRNA
in sculpting
the transcriptome

The role of miRNA in sculpting the transcriptome

Regulatory network view of miRNA impacts

Dynamic microRNA expression across diapause

Dynamic microRNA expression across diapause

Pieris napi

miRDeep2 identified 188 microRNAs

73 libraries (± 6.9 M reads / lib):

- 12 time points
- 2 tissues
- 3 replicates

Dynamic microRNA expression across diapause

OK, so some miRNAs are changing through time ...

Where are they targeting?
What are they doing?

What functional groups or
pathways might they
regulate?

miRNA target detection

- miRNAs primarily bind a very short, ± 7 bp region of the 3'UTR of mRNA
- This binding ultimately leads to a decrease of translated proteins
- There are 100,000's of 7 bp motifs in genome, of which miRNAs bind small fraction

Wheat et al., in submission

Large bioinformatic effect

>90% of miRNA literature in ecology and evolution uses miRanda to assess miRNA impacts...

Targetscan
using 6 species
3'UTRs
alignments

← Random sets

miRanda using
one species
3'UTRs

← Random sets

Wheat et al., in submission

So, why don't more people use Targetscan approach?

Running miRanda is quick and easy

- Download, load 3'UTR data from your species, load miRNA seed sites, run

Running TargetScan7 with alignments is a lot of work

- Download scripts, generate 3'UTR alignments for 7 species, load miRNA seed sites, etc.

Bioinformatic analysis of miRNA targets

Detecting miRNA expression changes is easy, but target detection is inherently very difficult

- Intersection
 - Comparison across bioinformatic tools
 - Revealed inconsistent results, primarily because used VERY different methods (e.g. using vs. not using alignments)
 - Developed novel metric for assess biological signal in results
 - Species comparisons for cross-check & generality

Sum: intersection across divergent methods, 1st principals metric, and comparative analysis revealed believable results

Review

Functional genomic tools for emerging model species

Erik Gudmunds,^{1,*} Christopher W. Wheat,² Abderrahman Khila,^{1,3} and Arild Husby ^{1,*}

Recent review covering diverse means of validation across diverse taxa

As genomics gets cheaper, invest more in validation instead of just more sequencing!!!!

A bit of bioinformatic wisdom

- Expect errors and noise
 - Analysis results need many rounds of refinement
 - Invoke biological causes of results last
- 70% of your time will be troubleshooting (AI might help reduce this)
 - This is normal, keep a notebook, intermediate files
- Fear the new and shiny programs that will simplify your life
 - 80% of all new software will not be usable
 - Un-installable, no manual, no test examples, not repeatable
 - Beware of these red flags, as many authors only seek a publication and won't help

Cookbooking ...

- Google and AI are your friends
- Use them, but don't trust them
- Test what you use, learn from it, build your own toolbox
- Copying without learning makes you easily replaced and open to massive errors

Keep good bioinformatic notes

- I keep a special file with commands I learned, like and validate
 - use it to quickly find commands, refresh memory
- Use positive and negative controls to test the output of the commands you run (like all experimental biology)
 - I call these sanity checks
 - Always test to make code is working correctly
 - Great reason to use > 1 method, right?
- Read up on good file structure, version control, and how to parallelize your commands

Publish your code, no matter how messy

Yours is without a doubt the worst code I've ever run

But it runs

Many different ways to make a pipeline

Sahraeian SME et al. 2017. Nat Commun.

Many tools, performance varies across species, samples.
This is no BEST tool or setting across all species

Differential expression detection
can vary by:

- Mapper
- Analysis software
- Reference genome
- Species

Raplee et al. 2019 J. Per. Med.

Analysis paralysis is common .. Which is the right way?

Just start by get through a single pipeline, start to end

Then try different approach to assess your first results

Used published data & code, then explore additional approaches

Experimental design matters: RNAseq and sample size

- Simple two group comparisons
 - 30 wild-type mice vs 30 mice in which one copy of a gene had been deleted
 - Full analysis: $n=30$ vs. $n=30$

FDR= % of DEG in subsample not found in full analysis

Sensitivity = % of genes found in subsample also seen in full analysis

Entering the mega-genomes era

An unprecedented opportunity for large scale errors?

- Unprecedented challenges:
 - Phylogenetic relationships
 - Genome evolution
 - Functional study of diverse adaptations

Comparative genomics commonly use annotations

Typical genome report comparing gene content among species

- Number of genes
- Rates of gene birth, death
- # of lineage specific genes

Gene birth-death dynamics: biased, artifacts, or meaningful results?

- Are changes in gene numbers across species meaningful?
- Fundamental and important evolutionary question
- Very difficult to assess accurately
 - Need good genomes, annotations
 - Then good analyses

Immunoglobulin heavy constant gamma gene evolution

Garzón-Ospina & Buitrago 2022

Are all annotations equal among species?

- Do species genomes differ in:
 - When they were sequenced, thus technology?
 - The quality of their assembly (e.g. N50, haploid state)?
 - How they did their annotation (proteins only vs. lots of RNAseq)?

Then resulting annotation protein sets likely differ due to technology,
not biology

Will this impact analyses that rely upon accurate protein sets?

Non-standard annotations introduce major artifacts

- Lineage specific genes inflated by
 - 10 to 1000's of genes, with increases up to 15 fold

Weisman et al. 2022. Current Biology

Comparative genomics and gene content evolution

families

Function	Emergent families
Wing morphogenesis	EOG86HJQQ
	EOG8TMTG9
	EOG80ZTDS
Exoskeleton development and pigmentation	EOG8Q2GZG
	EOG8RZ1DS
	EOG8VDSCK
	EOG8WHC14
	EOG8XPT03
	EOG83XXJ1
Adaptation to terrestrial environment	EOG82VBZ4
	EOG8PVRGC
	EOG8HTC7X
Larval behavior	EOG81K1SK

B Last Holometabolous
Common Ancestor:
10 emergent gene
families

Function	Emergent families
Anterior head segmentation	EOG8HDW8X
Nucleosome assembly	EOG8G1PZD
Transporter activity	EOG847J8K
Transferase activity	EOG8ZPH98
Serine-type endopeptidase	EOG8QJV3F

+ 5 families with no known function

C Last Lepidopteran
common ancestor:
1,038 emergent
gene families

“Although the majority of these gene sets were built using MAKER, variation in annotation pipelines and supporting data, introduce a potential source of technical gene content error in our analysis.”

Post-genomics challenge

“What we can measure is by definition uninteresting and what we are interested in is by definition immeasurable”

- Lewontin 1974

“What we understand of the genome is by definition uninteresting and what we are interested in is by definition very damn difficult to sequence and assemble and annotate and analyze at the genomic scale”

- Wheat 2015

Interrogate your results

“you need to be in charge of the analysis”

- The more you analyze your data, your confidence will grow
 - Let your findings talk to you in different ways
- Graph your results – visualize the patterns, assess 1st principals
 - Always start with PCA or MDS plot (how do your samples cluster?)
 - Compare with your different analysis results
- If you find interesting genes or patterns, can you test this hypothesis?
 - Using independent samples?
 - At a higher level of biological organization?
 - In some manipulative, functional way?

Molecular spandrels:

Story telling
vs.
Causal understanding

Genomics is full of adaptive stories

Treat your findings as hypotheses

How can you test these?

Never forget your origins and biases

**Genomic results are only hypotheses:
easy to get, likely misleading, need validation**
